Equivalence to Finite Automata

RE's: Introduction

- Regular expressions are an algebraic way to describe languages.
- They describe exactly the regular languages.
- If E is a regular expression, then L(E) is the language it defines.
- We'll describe RE's and their languages recursively.

RE's: Definition

- Basis 1: If a is any symbol, then a is a RE, and L(a) = {a}.
 - Note: {a} is the language containing one string, and that string is of length 1.
- **Basis 2:** ϵ is a RE, and $L(\epsilon) = {\epsilon}$.

Basis 3: \emptyset is a RE, and $L(\emptyset) = \emptyset$.

RE's: Definition - (2)

- ▶ Induction 1: If E_1 and E_2 are regular expressions, then E_1+E_2 is a regular expression, and $L(E_1+E_2) = L(E_1) \cup L(E_2)$.
- Induction 2: If E_1 and E_2 are regular expressions, then E_1E_2 is a regular expression, and $L(E_1E_2) = L(E_1)L(E_2)$.

Concatenation : the set of strings wx such that w Is in $L(E_1)$ and x is in $L(E_2)$.

RE's: Definition - (3)

Induction 3: If E is a RE, then E* is a RE, and L(E*) = (L(E))*.

Closure, or "Kleene closure" = set of strings $w_1w_2...w_n$, for some $n \ge 0$, where each w_i is in L(E). Note: when n=0, the string is ϵ .

6

Precedence of Operators

- Parentheses may be used wherever needed to influence the grouping of operators.
- Order of precedence is * (highest), then concatenation, then + (lowest).

Examples: RE's

- ► L(01) = {01}.
- ▶ $L(01+0) = \{01, 0\}.$
- ► $L(O(1+0)) = \{01, 00\}.$
 - Note order of precedence of operators.
- ► $L(0^*) = \{\epsilon, 0, 00, 000, ... \}.$
- L((0+10)*(e+1)) = all strings of 0's and 1's without two consecutive 1's.

Equivalence of RE's and Automata

- We need to show that for every RE, there is an automaton that accepts the same language.
 - > Pick the most powerful automaton type: the ϵ -NFA.
- And we need to show that for every automaton, there is a RE defining its language.
 - Pick the most restrictive type: the DFA.

Converting a RE to an ϵ -NFA

- Proof is an induction on the number of operators (+, concatenation, *) in the RE.
- We always construct an automaton of a special form (next slide).

RE to ϵ -NFA: Basis

Symbol a:

► E:

► Ø:

DFA-to-RE

- A strange sort of induction.
- States of the DFA are assumed to be 1,2,...,n.
- We construct RE's for the labels of restricted sets of paths.
 - Basis: single arcs or no arc at all.
 - Induction: paths that are allowed to traverse next state in order.

k-Paths

- A k-path is a path through the graph of the DFA that goes though no state numbered higher than k.
- Endpoints are not restricted; they can be any state.

Example: k-Paths

0-paths from 2 to 3: RE for labels = $\mathbf{0}$.

1-paths from 2 to 3: RE for labels = 0+11.

2-paths from 2 to 3: RE for labels = (**10**)***0**+**1**(**01**)***1**

3-paths from 2 to 3: RE for labels = ??

k-Path Induction

- Let R_{ij}^k be the regular expression for the set of labels of k-paths from state i to state j.
- **Basis:** k=0. $R_{ij}^{0} = sum of labels of arc from i to j.$
 - \blacktriangleright Ø if no such arc.
 - ▶ But add ∈ if i=j.

Example: Basis

$$R_{12}^{0} = \mathbf{0}.$$

$$R_{11}^{0} = \mathbf{0} + \mathbf{\epsilon} = \mathbf{\epsilon}.$$

k-Path Inductive Case

A k-path from i to j either:

1. Never goes through state k, or

2. Goes through k one or more times.

 $R_{ij}^{k} = R_{ij}^{k-1} + R_{ik}^{k-1} (R_{kk}^{k-1})^{*} R_{kj}^{k-1}.$

////Goes from
i to k the
first time/Zero or
more times
from k to kThen, from
k to j

Final Step

- The RE with the same language as the DFA is the sum (union) of R_{ij}ⁿ, where:
 - 1. n is the number of states; i.e., paths are unconstrained.
 - 2. i is the start state.
 - 3. j is one of the final states.

Example

$$R_{23}^{3} = R_{23}^{2} + R_{23}^{2}(R_{33}^{2})^{*}R_{33}^{2} = R_{23}^{2}(R_{33}^{2})^{*}$$

$$R_{23}^2 = (10)^*0 + 1(01)^*1$$

$$R_{33}^2 = 0(01)^*(1+00) + 1(10)^*(0+11)$$

$$R_{23}^{3} = [(10)^{*}0 + 1(01)^{*}1] [(0(01)^{*}(1+00) + 1(10)^{*}(0+11))]^{*}$$

 $\mathbf{0}$

Summary

Each of the three types of automata (DFA, NFA, ε-NFA) we discussed, and regular expressions as well, define exactly the same set of languages: the regular languages.

Algebraic Laws for RE's

- Union and concatenation behave sort of like addition and multiplication.
 - + is commutative and associative; concatenation is associative.
 - Concatenation distributes over +.
 - **Exception:** Concatenation is not commutative.

Identities and Annihilators

▶ R + ∅ = R.

- \triangleright ϵ is the identity for concatenation.
 - \blacktriangleright $\epsilon R = R\epsilon = R.$
- \blacktriangleright Ø is the annihilator for concatenation.

 $\triangleright \emptyset R = R \emptyset = \emptyset.$
